## S. 1 DERIVATION OF RESAMPLING MIS WEIGHTS

In this section we first derive the generalized Talbot MIS (Equation 36) and Pairwise MIS (Equation 37, Equation 38) weights from the requirement that the resampling weights $w_{i}$ given by Equation 19 must have a finite upper bound.

We then derive the upper bounds for the resampling weights $w_{i}$ with the above MIS weights schemes, and for variants of the MIS weights that use tractable PDFs $p_{i}$ instead of $\hat{p}_{i}$.

We assume that of the $M$ input samples $X_{i}$, indices in the set $R$ are canonical (Definition 5.2), i.e., their domain is $\Omega$, the shift mapping

is identity, and the target density $\hat{p}_{i}=\hat{p}$. The number of canonical samples is denoted $|R|$.

## S.1.1 Generalizing Talbot MIS Weights

We first require that the resampling weights stay bounded, and derive MIS weights $m_{i}$ that fulfill this condition. Denote $Y_{i}=T_{i}\left(X_{i}\right)$ and assume that $Y_{i} \in T_{i}\left(\operatorname{supp} X_{i}\right)$. The resampling weight of $X_{i}$ is then, by Equation 19,

$$
\begin{equation*}
w_{i}=m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right| \tag{S.1}
\end{equation*}
$$

Assuming that $\hat{p}_{i}\left(X_{i}\right) W_{i} \leq C_{i}$, we can bound the above as

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \frac{\hat{p}\left(Y_{i}\right) \hat{p}_{i}\left(X_{i}\right) W_{i}}{\hat{p}_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right|  \tag{S.2}\\
& \leq m_{i}\left(Y_{i}\right) \cdot \frac{\hat{p}\left(Y_{i}\right) C_{i}}{\hat{p}_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right| . \tag{S.3}
\end{align*}
$$

We require this to be at most some $\tilde{C}_{i}$, which we may choose freely as long as we still find suitable functions $m_{i}$. Then, $w_{i} \leq \tilde{C}_{i}$ will also hold:

$$
\begin{equation*}
w_{i} \leq m_{i}\left(Y_{i}\right) \cdot \frac{\hat{p}\left(Y_{i}\right) C_{i}}{\hat{p}_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right| \leq \tilde{C}_{i} \tag{S.4}
\end{equation*}
$$

The latter inequality is equivalent to

$$
\begin{equation*}
m_{i}\left(Y_{i}\right) \leq \frac{\tilde{C}_{i}}{C_{i}} \frac{\hat{p}_{i}\left(X_{i}\right)\left|\frac{\partial Y_{i}}{\partial X_{i}}\right|^{-1}}{\hat{p}\left(Y_{i}\right)} \tag{S.5}
\end{equation*}
$$

We observe that if $j$ is any canonical index, then we have $\hat{p}\left(Y_{i}\right)=$ $\hat{p}_{j}\left(T_{j}^{-1}\left(Y_{i}\right)\right)\left|\frac{\partial T_{j}^{-1}}{\partial Y_{i}}\right|$, and the numerator and denominator begin to look similar:

$$
\begin{equation*}
m_{i}\left(Y_{i}\right) \leq \frac{\tilde{C}_{i}}{C_{i}} \frac{\hat{p}_{i}\left(T_{i}^{-1}\left(Y_{i}\right)\right)\left|\frac{\partial T_{i}^{-1}}{\partial Y_{i}}\right|}{\hat{p}_{j}\left(T_{j}^{-1}\left(Y_{i}\right)\right)\left|\frac{\partial T_{j}^{-1}}{\partial Y_{i}}\right|}=\frac{\tilde{C}_{i}}{C_{i}} \hat{p}_{\leftarrow i}\left(Y_{i}\right) . \tag{S.6}
\end{equation*}
$$

Writing the expressions in terms of $\hat{p}_{\leftarrow i}$ and $\hat{p}_{\leftarrow j}$ is justified since $Y_{i}=T_{i}\left(X_{i}\right)$ was sampled (hence $\left.Y_{i} \in T_{i}\left(\operatorname{supp} X_{i}\right)\right)$, which implies $Y_{i} \in \operatorname{supp} \hat{p}$. Since $j$ is a canonical index, $\operatorname{supp} \hat{p} \subset \operatorname{supp} X_{j}=$ $\operatorname{supp} T_{j}\left(\operatorname{supp} X_{j}\right)$, and hence $Y_{i} \in \operatorname{supp} T_{j}\left(X_{j}\right)$.
If $m_{i}$ is such that it fulfills the above inequality but with a larger denominator, it will also fulfill the above inequality. We make the
denominator of $m_{i}$ symmetric by summing over all indices $j \in$ $\{1, \ldots, M\}$. We additionally choose $\tilde{C}_{i}=C_{i}$, leading to

$$
\begin{equation*}
m_{i}(y)=\frac{\hat{p}_{\leftarrow i}(y)}{\sum_{j=1}^{M} \hat{p}_{\leftarrow j}(y)} . \tag{S.7}
\end{equation*}
$$

These $m_{i}$ fulfill Equation 20 (see the definition of $\hat{p}_{\leftarrow i}$, Equation 35) and are valid, non-negative resampling MIS weights.

## S.1.2 Generalizing Pairwise MIS Weights

In order to derive the generalized Pairwise MIS weights, we proceed as before until Equation S.5,

$$
\begin{equation*}
m_{i}\left(Y_{i}\right) \leq \frac{\tilde{C}_{i}}{C_{i}} \frac{\hat{p}_{\leftarrow i}\left(Y_{i}\right)}{\hat{p}\left(Y_{i}\right)} \tag{S.8}
\end{equation*}
$$

but then treat canonical samples $i \in R$ and non-canonical indices $i \notin R$ differently. Instead of including all the indices in the denominator like before, we only increase the denominator by the term corresponding to index $i$, with a positive multiplier $\alpha_{i}$. We set for non-canonical samples

$$
\begin{equation*}
m_{i}(y)=\frac{\tilde{C}_{i}}{C_{i}} \frac{\hat{p}_{\leftarrow i}(y)}{\hat{p}(y)+\alpha_{i} \hat{p}_{\leftarrow i}(y)} \quad \text { for } i \notin R, \tag{S.9}
\end{equation*}
$$

and observe that this choice fulfills Equation S.8. We still need $m_{i}$ to sum to 1 over the $i$ that can generate $y$, in order to fulfill Equation 20, so we simply divide the remainder uniformly to the canonical samples $i \in R$,

$$
\begin{equation*}
m_{i}(y)=\frac{1}{|R|}\left(1-\sum_{j \notin R} m_{j}(y)\right) \quad \text { if } \mathrm{i} \in \mathrm{R} . \tag{S.10}
\end{equation*}
$$

Different choices for $\tilde{C}_{i}$ and $\alpha_{i}$ yield a family of potential MIS weights: denoting $\beta_{i}=\tilde{C}_{i} / C_{i}$, we reach

$$
\begin{align*}
m_{i}(y) & =\frac{1}{|R|}\left(1-\sum_{j \notin R} \beta_{j} \frac{\hat{p}_{\leftarrow j}(y)}{\hat{p}(y)+\alpha_{j} \hat{p}_{\leftarrow j}(y)}\right)  \tag{S.11}\\
& =\frac{1}{|R|}\left(1-\sum_{j \notin R} \frac{\beta_{j}}{\alpha_{j}}+\sum_{j \notin R} \frac{\beta_{j}}{\alpha_{j}} \frac{\hat{p}(y)}{\hat{p}(y)+\alpha_{j} \hat{p}_{\leftarrow j}(y)}\right) \quad \text { if } \in R \\
m_{i}(y) & =\beta_{i} \frac{\hat{p}_{\leftarrow i}(y)}{\hat{p}(y)+\alpha_{i} \hat{p}_{\leftarrow i}(y)} \quad \text { if } i \notin R . \tag{S.12}
\end{align*}
$$

Restricting this family by requiring that the parameters do not depend on $i$, and denoting $\alpha_{i}=\alpha$ and $\kappa=\sum_{i \notin R} \beta_{i} / \alpha_{i}=(M-$ $|R|) \beta / \alpha$, we reach the family

$$
\begin{align*}
& m_{i}(y)=\frac{1}{|R|}\left(1-\kappa+\frac{\kappa}{M-|R|} \sum_{j \notin R} \frac{\hat{p}(y)}{\hat{p}(y)+\alpha \hat{p}_{\leftarrow j}(y)}\right) \text { if } i \in R  \tag{S.13}\\
& m_{i}(y)=\alpha \frac{\kappa}{M-|R|} \frac{\hat{p}_{\leftarrow i}(y)}{\hat{p}(y)+\alpha \hat{p}_{\leftarrow i}(y)} \quad \text { if } i \notin R . \tag{S.14}
\end{align*}
$$

Since MIS weights must be non-negative and sum to one, we must have $0 \leq m_{i} \leq 1$ for all $i$ and $y$. We must generally have $\kappa \leq 1$ since otherwise $m_{i}(y)$ could be negative in Equation S.13. Since $\alpha>0$ and we must have $m_{i}(y) \geq 0$ in Equation S.14, we must also have $0 \leq \kappa$. We have $0 \leq \kappa \leq 1$, and we interpret the above MIS weights as linear interpolation between uniformly choosing one of
the canonical samples ( $\kappa=0, m_{i}=1 /|R|$ for $i \in R, m_{i}=0$ for $i \notin R$ ), and a fundamental MIS scheme $(\kappa=1)$ parametrized by $\alpha$ :

$$
\begin{align*}
& m_{i}(y)=\frac{1}{|R|}\left(\frac{1}{M-|R|} \sum_{j \notin R} \frac{\hat{p}(y)}{\hat{p}(y)+\alpha \hat{p}_{\leftarrow j}(y)}\right) \quad \text { if } i \in R  \tag{S.15}\\
& m_{i}(y)=\alpha \frac{1}{M-|R|} \frac{\hat{p}_{\leftarrow i}(y)}{\hat{p}(y)+\alpha \hat{p}_{\leftarrow i}(y)} \quad \text { if } i \notin R . \tag{S.16}
\end{align*}
$$

The uniform case. To find a sensible value for $\alpha$ for the fundamental MIS scheme, we consider the simple case when all $X_{i}$ are i.i.d. with $\hat{p}_{i}=\hat{p}$ for all $i$. In this case, we have no reason to favor any of the samples and we should have $m_{1}=\cdots=m_{M}=1 / M$, yielding

$$
\begin{align*}
& m_{i}(y)=\frac{1}{|R|}\left(\frac{1}{M-|R|} \sum_{j \notin R} \frac{1}{1+\alpha}\right)=\frac{1}{M} \quad \text { if } i \in R  \tag{S.17}\\
& m_{i}(y)=\alpha \frac{1}{M-|R|} \frac{1}{1+\alpha}=\frac{1}{M} \quad \text { if } i \notin R, \tag{S.18}
\end{align*}
$$

from which we solve

$$
\begin{equation*}
\alpha=\frac{M}{|R|}-1 . \tag{S.19}
\end{equation*}
$$

In the fundamental case $\kappa=1$, we substitute $\alpha=M /|R|-1$ and reach

$$
\begin{align*}
& m_{i}(y)=\frac{1}{M-|R|} \sum_{j \notin R} \frac{\hat{p}(y)}{|R| \hat{p}(y)+(M-|R|) \hat{p}_{\leftarrow j}(y)} \quad \text { if } i \in R  \tag{S.20}\\
& m_{i}(y)=\frac{\hat{p}_{\leftarrow i}(y)}{|R| \hat{p}(y)+(M-|R|) \hat{p}_{\leftarrow i}(y)} \quad \text { if } i \notin R, \tag{S.21}
\end{align*}
$$

which we call uniform Pairwise MIS.
The defensive case. If we instead treat the canonical samples as more reliable than the other samples, we may interpolate the previous solution towards always choosing one of the canonical samples by keeping $\alpha=M /|R|-1$ and choosing $0 \leq \kappa<1$. One such a heuristic could be to ensure that the MIS weights of the canonical samples are always at least as large as those of the other samples. With $\alpha=M /|R|-1$, the canonical $m_{i}(y)$ cannot be less than $(1-\kappa) /|R|$ (set $\hat{p}_{j}(y) \rightarrow \infty$ in Equation S.13), and the non-canonical $m_{i}$ cannot exceed $\kappa /(M-|R|)\left(\right.$ set $\hat{p}_{\leftarrow i}(y) \rightarrow \infty$ in Equation S.14). These bounds can be made equal by choosing $(1-\kappa) /|R|=\kappa /(M-|R|)$, i.e., $\kappa=(M-|R|) / M$, which gives us the defensive generalized Pairwise MIS weights,

$$
\begin{align*}
& m_{i}(y)=\frac{1}{M}+\frac{1}{M} \sum_{j \notin R} \frac{\hat{p}(y)}{|R| \hat{p}(y)+(M-|R|) \hat{p}_{\leftarrow j}(y)} \quad \text { if } i \in R  \tag{S.22}\\
& m_{i}(y)=\frac{M-|R|}{M} \frac{\hat{p}_{\leftarrow i}(y)}{|R| \hat{p}(y)+(M-|R|) \hat{p}_{\leftarrow i}(y)} \quad \text { if } i \notin R . \tag{S.23}
\end{align*}
$$

## S.1.3 Resampling Weight Bounds

We next derive more accurate bounds for the resampling weights for our generalized Talbot and Pairwise MIS weights. In all cases we achieve the same bound, $C_{i} /|R|$, where $\hat{p}_{i}\left(X_{i}\right) W_{i} \leq C_{i}$.

Generalized Talbot MIS. A direct substitution of the Generalized Talbot MIS weights (Equation S.7) into the formula of $w_{i}$ (Equation S.1) yields, assuming that $Y_{i}$ exists (otherwise $w_{i}=0$ ),

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.24}\\
& =\left(\frac{\hat{p}_{\leftarrow i}\left(Y_{i}\right)}{\sum_{j=1}^{M} \hat{p}_{\leftarrow j}\left(Y_{i}\right)}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.25}\\
& =\frac{\hat{p}_{i}\left(X_{i}\right)\left|\frac{\partial T_{i}^{-1}}{\partial Y_{i}}\right|}{\sum_{j \in R} \hat{p}_{\leftarrow j}\left(Y_{i}\right)+\sum_{j \notin R} \hat{p}_{\leftarrow j}\left(Y_{i}\right)} \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.26}\\
& =\frac{\hat{p}\left(Y_{i}\right)}{|R| \hat{p}\left(Y_{i}\right)+\sum_{j \notin R} \hat{p}_{\leftarrow j}\left(Y_{i}\right)} \cdot \hat{p}_{i}\left(X_{i}\right) W_{i}  \tag{S.27}\\
& \leq \frac{1}{|R|} \cdot C_{i}=\frac{C_{i}}{|R|} . \tag{S.28}
\end{align*}
$$

Generalized Pairwise MIS. We first cover the feasible parameter combinations $\alpha>0$ and $0 \leq \kappa \leq 1$ in one go, assuming that $\hat{p}_{i}\left(X_{i}\right) W_{i} \leq C_{i}$. For canonical samples $i \in R$, we have $\hat{p}_{i}=\hat{p}$ and $Y_{i}=T_{i}\left(X_{i}\right)=X_{i}$, we substitute Equation S. 13 and get the bound

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right|  \tag{S.29}\\
& =\frac{1}{|R|}\left(1-\kappa+\frac{\kappa}{M-|R|} \sum_{j \notin R} \frac{\hat{p}\left(Y_{i}\right)}{\hat{p}\left(Y_{i}\right)+\alpha \hat{p}_{\leftarrow j}\left(Y_{i}\right)}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot 1 \tag{S.30}
\end{align*}
$$

$$
\begin{equation*}
\leq \frac{1}{|R|}\left(1-\kappa+\frac{\kappa}{M-|R|} \sum_{j \notin R} \frac{\hat{p}\left(Y_{i}\right)}{\hat{p}\left(Y_{i}\right)}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \tag{S.31}
\end{equation*}
$$

$$
\begin{equation*}
\leq \frac{C_{i}}{|R|} \tag{S.32}
\end{equation*}
$$

For non-canonical samples $i \notin R$, assuming again $\hat{p}_{i}\left(X_{i}\right) W_{i} \leq C_{i}$, substituting Equation S.14, we get the bound

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right|  \tag{S.33}\\
& =\left(\alpha \frac{\kappa}{M-|R|} \frac{\hat{p}_{\leftarrow i}\left(Y_{i}\right)}{\hat{p}\left(Y_{i}\right)+\alpha \hat{p}_{\leftarrow i}\left(Y_{i}\right)}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial Y_{i}}{\partial X_{i}}\right|  \tag{S.34}\\
& =\alpha \frac{\kappa}{M-|R|} \frac{\hat{p}_{i}\left(X_{i}\right)}{\hat{p}\left(Y_{i}\right)+\alpha \hat{p}_{\leftarrow i}\left(Y_{i}\right)} \cdot \hat{p}\left(Y_{i}\right) W_{i}  \tag{S.35}\\
& \leq \alpha \frac{\kappa}{M-|R|} C_{i} . \tag{S.36}
\end{align*}
$$

In the case that $\alpha \leq M /|R|-1$, we simplify

$$
\begin{equation*}
w_{i} \leq \kappa \frac{C_{i}}{|R|} \leq \frac{C_{i}}{|R|} . \tag{S.38}
\end{equation*}
$$

## S.1.4 Tractable Marginal PDFs

Sometimes the PDFs of the input samples $X_{i}$ are tractable functions $p_{i}$. In that case, the PDFs $p_{i}$ may be used in place of the $\hat{p}_{i}$ in the MIS weight formulas, effectively replacing $\hat{p}_{\leftarrow i}$ with the following
" $p$ from $i$ ":

$$
p_{\leftarrow i}(y)= \begin{cases}p_{i}\left(T_{i}^{-1}(y)\right)\left|T_{i}^{-1 \prime}\right|(y), & \text { if } y \in \mathcal{D}\left(T_{i}^{-1}\right)  \tag{S.39}\\ 0 & \text { otherwise }\end{cases}
$$

resulting in the following expression for the generalized Talbot MIS:

$$
\begin{equation*}
m_{i}(y)=\frac{p_{\leftarrow i}\left(Y_{i}\right)}{\sum_{j=1}^{M} p_{\leftarrow j}\left(Y_{i}\right)} \tag{S.40}
\end{equation*}
$$

The Pairwise MIS expression additionally contains terms $\hat{p}(y)$ whose normalization may differ significantly from that of the PDFs $p_{i}$. As such, we suggest replacing the terms $\hat{p}(y)$ in the MIS with a fixed canonical importance sampler $c \in C$ that is reasonable for integrating $\hat{p}\left(\hat{p}(y) \leq C_{c} p_{c}(y)\right)$. We show the uniform case as an example of this translation to known PDFs:

$$
\begin{align*}
& m_{i}(y)=\frac{1}{M-|R|} \sum_{j \notin R} \frac{p_{c}(y)}{|R| p_{c}(y)+(M-|R|) p_{\leftarrow j}(y)} \quad \text { if } i \in R  \tag{S.41}\\
& m_{i}(y)=\frac{\hat{p}_{\leftarrow i}(y)}{|R| p_{c}(y)+(M-|R|) p_{\leftarrow i}(y)} \quad \text { if } i \notin R . \tag{S.42}
\end{align*}
$$

We then derive the resampling weight bounds for these updated formulas. Since the $p_{i}$ are tractable, we assume unbiased contribution weights $W_{i}=1 / p_{i}\left(X_{i}\right)$. We also assume that the canonical samples are reasonably importance sampled for $\hat{p}$, i.e., $\hat{p}(x) \leq C_{i} p_{i}(x)$ for all $i \in R$.

Talbot MIS. Substituting Equation S. 40 into Equation S.1, yields, remembering that $p_{\leftarrow j}(y)=p_{j}(y)$ for canonical $j$,

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.43}\\
& =\left(\frac{p_{\leftarrow i}\left(Y_{i}\right)}{\sum_{j=1}^{M} p_{\leftarrow j}\left(Y_{i}\right)}\right) \cdot \frac{\hat{p}\left(Y_{i}\right)}{p_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.44}\\
& =\frac{p_{i}\left(X_{i}\right)}{\sum_{j \in R} p_{\leftarrow j}\left(Y_{i}\right)+\sum_{j \notin R} p_{\leftarrow j}\left(Y_{i}\right)} \cdot \frac{\hat{p}\left(Y_{i}\right)}{p_{i}\left(X_{i}\right)}  \tag{S.45}\\
& =\frac{\hat{p}\left(Y_{i}\right)}{\sum_{j \in R} p_{j}\left(Y_{i}\right)+\sum_{j \notin R} p_{\leftarrow j}\left(Y_{i}\right)}  \tag{S.46}\\
& \leq \frac{\hat{p}\left(Y_{i}\right)}{\sum_{j \in R} p_{j}\left(Y_{i}\right)} \leq \frac{\hat{p}\left(Y_{i}\right)}{|R| \min _{j \in R} p_{j}\left(Y_{i}\right)}  \tag{S.47}\\
& =\frac{1}{|R|} \max _{j \in R} \frac{\hat{p}\left(Y_{i}\right)}{p_{j}\left(Y_{i}\right)} \leq \frac{1}{|R|} \max _{j \in R} C_{j} . \tag{S.48}
\end{align*}
$$

Pairwise MIS. We now derive bounds for the resampling weights in the case of Generalized Pairwise MIS weights with $0 \leq \alpha \leq$ $M /|R|-1$ and $0 \leq \kappa \leq 1$, using $p_{i}$ instead of $\hat{p}_{i}$.
If $i$ is a canonical index, we use Equation S .13 with $\hat{p}_{\leftarrow j}$ replaced with $p_{\leftarrow j}$ and $\hat{p}$ replaced with $p_{c}$. Noting that for canonical indices

$$
\begin{align*}
Y_{i} & =T_{i}\left(X_{i}\right)=X_{i}, \text { we reach } \\
& w_{i}=m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.49}\\
& =\frac{1}{|R|}\left(1-\kappa+\frac{\kappa}{M-|R|} \sum_{j \notin R} \frac{p_{c}\left(Y_{i}\right)}{p_{c}\left(Y_{i}\right)+\alpha p_{\leftarrow j}\left(Y_{i}\right)}\right) \cdot \frac{\hat{p}\left(Y_{i}\right)}{p_{i}\left(X_{i}\right)} \cdot 1  \tag{S.50}\\
& \leq \frac{1}{|R|}\left(1-\kappa+\frac{\kappa}{M-|R|} \sum_{j \notin R} 1\right) \cdot \frac{\hat{p}\left(X_{i}\right)}{p_{i}\left(X_{i}\right)}  \tag{S.51}\\
& =\frac{1}{|R|} \cdot \frac{\hat{p}\left(X_{i}\right)}{p_{i}\left(X_{i}\right)} \leq \frac{C_{i}}{|R|} . \tag{S.52}
\end{align*}
$$

Similarly, for non-canonical $i$ we use Equation S. 14 with the same substitutions and reach

$$
\begin{align*}
w_{i} & =m_{i}\left(Y_{i}\right) \cdot \hat{p}\left(Y_{i}\right) W_{i} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.53}\\
& =\left(\alpha \frac{\kappa}{M-|R|} \frac{p_{\leftarrow i}\left(Y_{i}\right)}{p_{c}\left(Y_{i}\right)+\alpha p_{\leftarrow i}\left(Y_{i}\right)}\right) \cdot \frac{\hat{p}\left(Y_{i}\right)}{p_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.54}\\
& =\left(\alpha \frac{\kappa}{M-|R|} \frac{p_{i}\left(X_{i}\right)\left|\frac{\partial T_{i}^{-1}}{\partial Y_{i}}\right|}{p_{c}\left(Y_{i}\right)+\alpha p_{\leftarrow i}\left(Y_{i}\right)}\right) \cdot \frac{\hat{p}\left(Y_{i}\right)}{p_{i}\left(X_{i}\right)} \cdot\left|\frac{\partial T_{i}}{\partial X_{i}}\right|  \tag{S.55}\\
& =\alpha \frac{\kappa}{M-|R|} \frac{\hat{p}\left(Y_{i}\right)}{p_{c}\left(Y_{i}\right)+\alpha p_{\leftarrow i}\left(Y_{i}\right)} \leq \alpha \frac{\kappa}{M-|R|} \frac{\hat{p}\left(Y_{i}\right)}{p_{c}\left(Y_{i}\right)}  \tag{S.56}\\
& \leq \alpha \frac{\kappa}{M-|R|} C_{c} \leq\left(\frac{M}{|R|}-1\right) \frac{1}{M-|R|} C_{c}=\frac{C_{c}}{|R|} . \tag{S.57}
\end{align*}
$$

We can combine the above results into a single, slightly looser bound that works for any $i$ and both MIS weight families (Talbot and Pairwise) when used with tractable PDFs:

$$
\begin{equation*}
w_{i} \leq \frac{1}{|R|} \max _{j \in R} C_{j} \tag{S.58}
\end{equation*}
$$

## S. 2 CONVERGENCE WITH DEPENDENT SAMPLES

In Section 5.7, we assume dependent input samples such that
(1) the ratio of canonical samples, $|R| / M$, never falls below a positive constant $\gamma$ for large enough $M$,
(2) there exists a $C>0$ such that $w_{i} \leq C /|R|$ for all $i$,
(3) there exists a non-negative sequence $b_{k}$ such that the correlation $\rho_{i, i+k} \leq b_{k}$ for all $i$, and $b_{k} \rightarrow 0$.

Then,

$$
\begin{equation*}
\operatorname{Var}\left[\sum_{i=1}^{M} w_{i}\right]=\sum_{i=1}^{M} \operatorname{Var}\left[w_{i}\right]+2 \sum_{i=1}^{M} \sum_{k=1}^{M-i} \operatorname{Cov}\left(w_{i}, w_{i+k}\right) \tag{S.59}
\end{equation*}
$$

converges to zero:
The convergence of the first term is proved in Section 5.7, and for the second term we have

$$
\begin{align*}
& \sum_{i=1}^{M} \sum_{k=1}^{M-i} \operatorname{Cov}\left(w_{i}, w_{i+k}\right)=\sum_{i=1}^{M} \sum_{k=1}^{M-i} \rho_{i, i+k} \sqrt{\operatorname{Var} w_{i} \operatorname{Var} w_{i+k}}  \tag{S.60}\\
& \quad \leq \sum_{i=1}^{M} \sum_{k=1}^{M-i} \max \left(0, \rho_{i, i+k}\right) \frac{C^{2}}{4|R|^{2}} \leq \sum_{i=1}^{M} \sum_{k=1}^{M-i} b_{k} \frac{C^{2}}{4 M^{2} \gamma^{2}}  \tag{S.61}\\
& \quad=\frac{C^{2}}{4 \gamma^{2}} \frac{1}{M^{2}} \sum_{k=1}^{M} \sum_{i=1}^{M-k} b_{k}=\frac{C^{2}}{4 \gamma^{2}} \frac{1}{M^{2}} \sum_{k=1}^{M}(M-k) b_{k}  \tag{S.62}\\
& \quad \leq \frac{C^{2}}{4 \gamma^{2}}\left(\frac{1}{M} \sum_{k=1}^{M} b_{k}\right) \xrightarrow{M \rightarrow \infty} 0 . \tag{S.63}
\end{align*}
$$

To reach Equation S.61, we used Popoviciu's inequality: since $0 \leq w_{i} \leq C /|R|$, we know $\operatorname{Var} w_{i} \leq \frac{C^{2}}{4|R|^{2}}$. The next step used $|R| / M \geq \gamma$, and for Equation S .62 we reversed the summation order: $\sum_{i=1}^{M} \sum_{k=1}^{M-i}=\sum_{k=1}^{M} \sum_{i=1}^{M-k}$. The mean of $b_{k}$ converges to zero since $b_{k}$ converges to zero, and Equation S. 63 implies

$$
\operatorname{Var}\left[\sum_{i=1}^{M} w_{i}\right] \xrightarrow{M \rightarrow \infty} 0 .
$$

We can slightly generalize the result: assume that

$$
\begin{equation*}
|R| \geq c_{M} M^{0.5} \sqrt{\sum_{i=1}^{M} b_{i}} \tag{S.64}
\end{equation*}
$$

where $\left(c_{M}\right)$ is any non-negative sequence that approaches infinity. Then, like above,

$$
\begin{align*}
& \sum_{i=1}^{M} \sum_{k=1}^{M-i} \operatorname{Cov}\left(w_{i}, w_{i+k}\right) \leq \sum_{i=1}^{M} \sum_{k=1}^{M-i} \max \left(0, \rho_{i, i+k}\right) \frac{C^{2}}{4|R|^{2}}  \tag{S.65}\\
& \quad=\sum_{k=1}^{M} \sum_{i=1}^{M-k} \max \left(0, \rho_{i, i+k}\right) \frac{C^{2}}{4|R|^{2}} \leq \sum_{k=1}^{M}(M-k) b_{k} \frac{C^{2}}{4|R|^{2}}  \tag{S.66}\\
& \quad \leq\left(\sum_{k=1}^{M} b_{k}\right) \frac{M C^{2}}{4|R|^{2}} \leq\left(\sum_{k=1}^{M} b_{k}\right) \frac{M C^{2}}{4 c_{M}^{2} M\left(\sum_{i=1}^{M} b_{i}\right)}  \tag{S.67}\\
& \quad=\frac{C^{2}}{4 c_{M}^{2}} \xrightarrow{M \rightarrow \infty} 0 \tag{S.68}
\end{align*}
$$

## S. 3 PRIMARY SAMPLE SPACE

Performing integration in a Monte Carlo setting typically starts from primary sample sequences, i.e., streams of random numbers $\overline{\mathbf{U}}=\left(U_{1}, U_{2}, \ldots\right)$, where $U_{i} \in[0,1)$ are uniformly distributed. Each $\overline{\mathrm{U}}$ is used to estimate a contribution $F(\overline{\mathbf{U}})$, and the Monte Carlo integration result is

$$
\begin{equation*}
I=\mathbb{E}[F(\overline{\mathbf{U}})]=\int_{\mathcal{U}} F(\overline{\mathbf{u}}) \mathrm{d} \overline{\mathbf{u}} . \tag{S.69}
\end{equation*}
$$

A unidirectional path tracer builds a sequence of paths of different lengths from the random sequences $\bar{U}$. Often, the path tracer produces, for each length $d, N$ paths $X_{d, n} \in \Omega_{d}$ by different strategies. Here, $\Omega_{d}$ is the space of all paths of length $d$. $N$ is often 2 , and the paths $X_{d, n}$ with different $n$ correspond to a next-event-estimation path connected to a random light, and path continued to a direction importance sampled according to the BSDF. The paths $X_{d, n}$ are functions of $\overline{\mathbf{U}}$, i.e., $X_{d, n}=x_{d, n}(\overline{\mathbf{U}})$.
The total path contribution is the sum of the integrals of the fixed-length path contributions,

$$
\begin{equation*}
I=\sum_{d=1}^{\infty} \int_{\Omega_{d}} f(x) \mathrm{d} x \tag{S.70}
\end{equation*}
$$

We factor in the MIS weights $\omega_{d, n}$ of the $n$ sampling strategies and reach

$$
\begin{align*}
I & =\sum_{d=1}^{\infty} \int_{\Omega_{d}}\left[\sum_{n=1}^{N} \omega_{d, n}(x)\right] f(x) \mathrm{d} x  \tag{S.71}\\
& =\sum_{d=1}^{\infty} \sum_{n=1}^{N} \int_{\Omega_{d}} \omega_{d, n}(x) f(x) \mathrm{d} x . \tag{S.72}
\end{align*}
$$

We assume for each term a proper importance sampler that produces paths $X_{d, n} \in \Omega_{d}$ with density $p_{d, n}$. We assume that $\omega_{d, n}(x)=0$ whenever $p_{d, n}(x)=0$ to retain the partition of unity. This yields us

$$
\begin{equation*}
I=\sum_{d=1}^{\infty} \sum_{n=1}^{N} \mathbb{E}\left[\omega_{d, n}\left(X_{d, n}\right) \frac{f\left(X_{d, n}\right)}{p_{d, n}\left(X_{d, n}\right)}\right] . \tag{S.73}
\end{equation*}
$$

Since the $X_{d, n}$ are generated from the random variables $\overline{\mathbf{U}}$ by $X_{d, n}=$ $x_{d, n}(\overline{\mathbf{U}})$, we may write

$$
\begin{equation*}
I=\sum_{d=1}^{\infty} \sum_{n=1}^{N} \mathbb{E}\left[\omega_{d, n}\left(x_{d, n}(\overline{\mathbf{U}})\right) \frac{f\left(x_{d, n}(\overline{\mathbf{U}})\right)}{p_{d, n}\left(x_{d, n}(\overline{\mathbf{U}})\right)}\right] . \tag{S.74}
\end{equation*}
$$

The fact that many $\overline{\mathbf{U}}$ may lead to the same path $X_{d, n}$ does not complicate this fact. We then write the expectations as integrals and reach

$$
\begin{align*}
I & =\sum_{d=1}^{\infty} \sum_{n=1}^{N} \int_{\mathscr{U}} \omega_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right) \frac{f\left(x_{d, n}(\overline{\mathbf{u}})\right)}{p_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right)} \mathrm{d} \overline{\mathbf{u}}  \tag{S.75}\\
& =\int_{\mathscr{U}} \sum_{d=1}^{\infty} \sum_{n=1}^{N} \omega_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right) \frac{f\left(x_{d, n}(\overline{\mathbf{u}})\right)}{p_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right)} \mathrm{d} \overline{\mathbf{u}} . \tag{S.76}
\end{align*}
$$

This yields us the $F$ for Equation S.69,

$$
\begin{equation*}
F(\overline{\mathbf{u}})=\sum_{d=1}^{\infty} \sum_{n=1}^{N} \omega_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right) \frac{f\left(x_{d, n}(\overline{\mathbf{u}})\right)}{p_{d, n}\left(x_{d, n}(\overline{\mathbf{u}})\right)} \tag{S.77}
\end{equation*}
$$

```

```

## S. 4 RESERVOIR STORAGE

We provide an overview of our reservoir data structure in Algorithm 1. A key takeaway is that most of the storage is used for enabling a reconnection to the base path's vertex: reconnection requires evaluating offset path's visibility to the reconnection vertex and the BSDF towards base path's next vertex. Note that our reservoir data structure is unoptimized and highly compressible-realtime use would allow lossy compression for increased performance, but our prototype implementation does not do it.

## S. 5 PROOFS OF THEOREMS

## S.5.1 Unbiased Contribution Weights (Theorem A.1)

Proof of Theorem A.1. Assume Item 1: $W$ and $X$ are such that $\mathbb{E}[f(X) W]=\int_{\text {supp } X} f(x) \mathrm{d} x$ for any integrable $f$. We prove Item 2: Let $A \subset \operatorname{supp}(X)$ be measurable. Then,

$$
\begin{align*}
& \int_{A} p_{X}(x) \mathrm{d} x=\int_{\operatorname{supp}(X)} \mathbb{1}_{A}(x) p_{X}(x) \mathrm{d} x \\
& =\mathbb{E}\left[\mathbb{1}_{A}(X) p_{X}(X) W\right]=\mathbb{E}\left[\mathbb{E}\left[\mathbb{1}_{A}(X) p_{X}(X) W \mid X\right]\right]  \tag{S.78}\\
& =\mathbb{E}\left[\mathbb{1}_{A}(X) p_{X}(X) \mathbb{E}[W \mid X]\right] \\
& =\int_{A} p_{X}(x)^{2} \mathbb{E}[W \mid X=x] \mathrm{d} x .
\end{align*}
$$

Since this holds for all measurable $A \subset \operatorname{supp}(X)$, we must have, almost everywhere in $\operatorname{supp}(X)$,

$$
\begin{equation*}
p_{X}(x)=p_{X}(x)^{2} \mathbb{E}[W \mid X=x] . \tag{S.79}
\end{equation*}
$$

Since $p_{X}(x)>0$ in $\operatorname{supp}(X)$, we deduce $\mathbb{E}[W \mid X=x]=1 / p_{X}(x)$ a.e. in $\operatorname{supp}(X)$.

Next, assume Item 2: $W$ and $X$ are such that $\mathbb{E}[W \mid X=x]=$ $1 / p_{X}(x)$ a.e. in $\operatorname{supp}(X)$. We prove Item 1: Let $f: \Omega \rightarrow \mathbb{R}$ be integrable. We have

$$
\begin{array}{r}
\mathbb{E}[f(X) W]=\mathbb{E}[\mathbb{E}[f(X) W \mid X]]=\mathbb{E}[f(X) \mathbb{E}[W \mid X]] \\
=\mathbb{E}\left[\frac{f(X)}{p_{X}(X)}\right]=\int_{\operatorname{supp}(X)} f(x) \mathrm{d} x . \tag{S.80}
\end{array}
$$

S.5.2 Asymptotic Sample Distribution (Theorem A.2)

We start from Equation 22 and derive the equality

$$
\begin{equation*}
\sum_{i=1}^{M} w_{i}=\hat{p}(Y) W_{Y} . \tag{S.81}
\end{equation*}
$$

We then prove the following, slightly more general result: If $\left(Y_{M}\right)_{M=M_{0}}^{\infty}$ is a sequence of random variables that fulfill $\operatorname{supp} \hat{p} \subset \operatorname{supp} Y_{M}$ (Equation 57) and have non-negative unbiased contribution weights $W_{Y_{M}}$ such that

$$
\begin{equation*}
\operatorname{Var}\left[\hat{p}\left(Y_{M}\right) W_{Y_{M}}\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.82}
\end{equation*}
$$

(a generalization of Equation 58), then the conclusions of Theorem A. 2 hold:

Proof of Theorem A. 2 (Item 1), Equation 59. Let $\varepsilon>0$ be given. We prove that

$$
\operatorname{Pr}\left[\left|p_{Y}(Y)-\bar{p}(Y)\right|>\varepsilon\right] \xrightarrow{M \rightarrow \infty} 0:
$$

For any $0<\varepsilon_{2}<1$ we have

$$
\begin{aligned}
& \operatorname{Pr}\left[\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right]=A+B+C, \quad \text { where } \\
& A=\operatorname{Pr}\left[\left(\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right) \wedge\left(p_{Y}(Y) \geq \frac{1}{\varepsilon_{2}}\right)\right], \\
& B=\operatorname{Pr}\left[\left(\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right) \wedge\left(1<p_{Y}(Y)<\frac{1}{\varepsilon_{2}}\right)\right], \\
& C=\operatorname{Pr}\left[\left(\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right) \wedge\left(p_{Y}(Y) \leq 1\right)\right] .
\end{aligned}
$$

Since $\operatorname{Pr}[X \wedge Y] \leq \operatorname{Pr}[Y]$ and $p_{Y}$ integrates to 1 , we have

$$
A \leq \operatorname{Pr}\left[p_{Y}(Y) \geq \frac{1}{\varepsilon_{2}}\right] \leq \varepsilon_{2}
$$

(otherwise $p_{Y}$ would integrate to more than $\varepsilon_{2} \cdot 1 / \varepsilon_{2}=1$ ). Since in case $B$ we have $1 / p_{Y}(Y)>\varepsilon_{2}$, we get

$$
\begin{aligned}
B & =\operatorname{Pr}\left[\left(\left|\bar{p}(Y)-p_{Y}(Y)\right| \varepsilon_{2}>\varepsilon \cdot \varepsilon_{2}\right) \wedge\left(1<p_{Y}(Y)<\frac{1}{\varepsilon_{2}}\right)\right] \\
& \leq \operatorname{Pr}\left[\left(\frac{\left|\bar{p}(Y)-p_{Y}(Y)\right|}{p_{Y}(Y)}>\varepsilon \cdot \varepsilon_{2}\right) \wedge\left(1<p_{Y}(Y)<\frac{1}{\varepsilon_{2}}\right)\right] \\
& \leq \operatorname{Pr}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|>\varepsilon \cdot \varepsilon_{2}\right] .
\end{aligned}
$$

Similarly, in case $C$ we have $1 / p_{Y}(Y) \geq 1$, and thus

$$
\begin{aligned}
C & =\operatorname{Pr}\left[\left(\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right) \wedge\left(p_{Y}(Y) \leq 1\right)\right] \\
& \leq \operatorname{Pr}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|>\varepsilon\right] .
\end{aligned}
$$

By Chebyshev's inequality, we have for any $s>0$ (such as $s=\varepsilon \cdot \varepsilon_{2}$ for $B$ and $s=\epsilon$ for $C$ ), that

$$
\begin{equation*}
\operatorname{Pr}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|>s\right]<\frac{1}{s^{2}} \mathbb{E}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|^{2}\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.84}
\end{equation*}
$$

and thus

$$
\begin{equation*}
0 \leq \lim _{M \rightarrow \infty} A+B+C \leq \varepsilon_{2}+0+0 \xrightarrow{\varepsilon_{2} \rightarrow 0} 0 \tag{S.85}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
\operatorname{Pr}\left[\left|\bar{p}(Y)-p_{Y}(Y)\right|>\varepsilon\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.86}
\end{equation*}
$$

Proof of Theorem A. 2 (Item 2), Equation 60. By assumption, we have $\operatorname{supp} \hat{p} \subset \operatorname{supp} Y_{M}$ for each $M$. Dropping the index $M$ for brevity, we thus have

$$
\begin{equation*}
\mathbb{E}\left[\frac{\hat{p}(Y)}{p_{Y}(Y)}\right]=\int_{\text {supp } Y} \hat{p}(y) \mathrm{d} y=\|\hat{p}\| . \tag{S.87}
\end{equation*}
$$

Thus, we deduce from the law of total variance that

$$
\begin{align*}
\operatorname{Var}\left[\hat{p}(Y) W_{Y}\right] & =\mathbb{E}\left[\operatorname{Var}\left[\hat{p}(Y) W_{Y} \mid Y\right]\right]+\operatorname{Var}\left[\mathbb{E}\left[\hat{p}(Y) W_{Y} \mid Y\right]\right] \\
& \geq \operatorname{Var}\left[\mathbb{E}\left[\hat{p}(Y) W_{Y} \mid Y\right]\right]=\operatorname{Var}\left[\frac{\hat{p}(Y)}{p_{Y}(Y)}\right] \\
& =\mathbb{E}\left[\left|\frac{\hat{p}(Y)}{p_{Y}(Y)}-\|\hat{p}\|\right|^{2}\right] . \tag{S.88}
\end{align*}
$$

Since $\operatorname{Var}\left[\hat{p}(Y) W_{Y}\right]$ by assumption tends to 0 , we reach convergence of $p_{Y}$ to $\bar{p}$ in mean square:

$$
\begin{align*}
\mathbb{E}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|^{2}\right] & =\frac{1}{\|\hat{p}\|^{2}} \mathbb{E}\left[\left|\frac{\hat{p}(Y)}{p_{Y}(Y)}-\|\hat{p}\|\right|^{2}\right] \\
& \leq \frac{1}{\|\hat{p}\|^{2}} \operatorname{Var}\left[\hat{p}(Y) W_{Y}\right] \xrightarrow{M \rightarrow \infty} 0 . \tag{S.89}
\end{align*}
$$

Proof of Theorem A. 2 (Item 3), Equation 61. By the CauchySchwarz inequality, convergence of a random variable in meansquare implies convergence in mean:

$$
\begin{equation*}
\mathbb{E}\left[\left|Z_{i}-Z_{\infty}\right|\right] \leq \sqrt{\mathbb{E}\left[1^{2}\right]} \sqrt{\mathbb{E}\left[\left|Z_{i}-Z_{\infty}\right|^{2}\right]} \xrightarrow{i \rightarrow \infty} 0 \tag{S.90}
\end{equation*}
$$

By Equation 60, $\mathbb{E}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|\right] \xrightarrow{M \rightarrow \infty} 0$. Since we have supp $\hat{p} \subset$ $\operatorname{supp} Y$, we have $p_{Y}(y)-\hat{p}(y)=0-0$ outside of supp $Y$ for all $M$, and thus

$$
\begin{align*}
& \int_{\Omega}\left|p_{Y}(y)-\bar{p}(y)\right| \mathrm{d} y=\int_{\operatorname{supp} Y}\left|p_{Y}(y)-\bar{p}(y)\right| \mathrm{d} y \\
& =\mathbb{E}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-1\right|\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.91}
\end{align*}
$$

Proof of Theorem A. 2 (Item 4). Let $G$ be the set of $y \in \Omega$ for which $p_{Y_{M}}(y)$ converges, and let $g(y)$ be the limit, i.e.,

$$
\begin{equation*}
g(y)=\lim _{M \rightarrow \infty} p_{Y_{M}}(y) \quad \text { for all } y \in G \tag{S.92}
\end{equation*}
$$

All subsequences $p_{Y_{a_{k}}}(y)$ also converge pointwise to $g(y)$ in $G$. By Equation 61, $p_{Y}(y)$ converges to $\bar{p}$ in the Lebesgue $L^{1}$ sense:

$$
\begin{equation*}
\left\|\bar{p}(y)-p_{Y_{M}}(y)\right\|_{L^{1}}=\int_{\Omega}\left|\bar{p}(y)-p_{Y_{M}}(y)\right| \mathrm{d} y \xrightarrow{M \rightarrow \infty} 0 \tag{S.93}
\end{equation*}
$$

Since $p_{Y_{M}}$ converges to $\bar{p}$ in the $L^{1}$-norm, it converges also in the $L^{1}$-measure [Bartle 2014, p. 69]. Thus, it has a subsequence $p_{Y_{a_{k}}}$ that converges to $\bar{p}$ almost everywhere [Bartle 2014, p. 69]. But if $y \in G$, then $p_{Y_{a_{k}}}(y)$ also converges to $g(y)$, so we must have $g(y)=\bar{p}(y)$ almost everywhere in $G$.

Proof of Theorem A. 2 (Item 5). Let $X$ be distributed with PDF $\bar{p}$ and $A$ be an arbitrary measurable subset of $\Omega$. Then, by Theorem A. 2 (Item 3),

$$
\begin{aligned}
|\operatorname{Pr}[Y \in A]-\operatorname{Pr}[X \in A]| & =\left|\int_{A} p_{Y}(y) \mathrm{d} y-\int_{A} \bar{p}(y) \mathrm{d} y\right| \\
& \leq \int_{\Omega}\left|p_{Y}(y)-\bar{p}(y)\right| \mathrm{d} y \xrightarrow{M \rightarrow \infty} 0
\end{aligned}
$$

## S.5.3 Asymptotic Variance (Theorem A.3)

We first prove the support and then Item 1 - Item 3:

Proof of Theorem A.3, support. By assumption (Equation 57), $\operatorname{supp} \hat{p} \subset \operatorname{supp} Y_{M}$ for all $M$. We also assume $f \leq C_{f} \hat{p}$ for some $C_{f}>0$. Thus, $f(x)>0$ implies $\hat{p}(x)>0$, and we have supp $f \subset$ $\operatorname{supp} \hat{p} \subset \operatorname{supp} Y_{M}$.

Proof of Theorem A. 3 (Item 1), Equation 63 and Equation 64. We first prove convergence in mean square:

$$
\begin{aligned}
& \mathbb{E}\left[\left|f(Y) w_{Y}-\frac{f(Y)}{\bar{p}(Y)}\right|^{2}\right]=\mathbb{E}\left[\left|\frac{f(Y)}{\hat{p}(Y)} \sum_{i=1}^{M} w_{M, i}-\frac{f(Y)}{\bar{p}(Y)}\right|^{2}\right] \\
& =\mathbb{E}\left[\frac{f(Y)^{2}}{\hat{p}(Y)^{2}}\left|\sum_{i=1}^{M} w_{M, i}-\frac{\hat{p}(Y)}{\bar{p}(Y)}\right|^{2}\right]=\mathbb{E}\left[\frac{f(Y)^{2}}{\hat{p}(Y)^{2}}\left|\sum_{i=1}^{M} w_{M, i}-\|\hat{p}\|\right|^{2}\right] \\
& \leq C_{f}^{2} \mathbb{E}\left[\left|\sum_{i=1}^{M} w_{M, i}-\|\hat{p}\|\right|^{2}\right]=C_{f}^{2} \operatorname{Var}\left[\sum_{i=1}^{M} w_{M, i}\right] \xrightarrow{M \rightarrow \infty} 0 .
\end{aligned}
$$

Convergence in mean square implies convergence in mean and in probability. E.g., by Chebyshev's inequality, given $\varepsilon>0$, we have

$$
\operatorname{Pr}\left[\left|f(Y) W_{Y}-\frac{f(Y)}{\bar{p}(Y)}\right|>\varepsilon\right] \leq \frac{1}{\varepsilon^{2}} \mathbb{E}\left[\left|f(Y) W_{Y}-\frac{f(Y)}{\bar{p}(Y)}\right|^{2}\right] \xrightarrow{M \rightarrow \infty} 0
$$

Proof of Theorem A. 3 (Item 2), Equation 65. We proceed in three steps.

Step 1. We show that

$$
\begin{equation*}
\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.94}
\end{equation*}
$$

From the law of total variance we get

$$
\operatorname{Var}\left[f(Y) W_{Y}\right]=\operatorname{Var}\left[\mathbb{E}\left[f(Y) W_{Y} \mid Y\right]\right]+\mathbb{E}\left[\operatorname{Var}\left[f(Y) W_{Y} \mid Y\right]\right]
$$

which we rewrite as

$$
\begin{aligned}
\mathbb{E}\left[\operatorname{Var}\left[f(Y) W_{Y} \mid Y\right]\right] & =\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\mathbb{E}\left[f(Y) W_{Y} \mid Y\right]\right] \\
& =\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]
\end{aligned}
$$

Since a conditional variance is non-negative, and we have

$$
\begin{align*}
0 & \leq \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]=\mathbb{E}\left[\operatorname{Var}\left[f(Y) W_{Y} \mid Y\right]\right] \\
& =\mathbb{E}\left[\operatorname{Var}\left[\left.\frac{f(Y)}{p_{Y}(Y)} \sum_{i=1}^{M} w_{M, i} \right\rvert\, Y\right]\right]=\mathbb{E}\left[\frac{f(Y)^{2}}{\hat{p}(Y)^{2}} \operatorname{Var}\left[\sum_{i=1}^{M} w_{M, i} \mid Y\right]\right] \\
& \leq C_{f}^{2} \mathbb{E}\left[\operatorname{Var}\left[\sum_{i=1}^{M} w_{M, i} \mid Y\right]\right]  \tag{S.95}\\
& \leq C_{f}^{2}\left(\mathbb{E}\left[\operatorname{Var}\left[\sum_{i=1}^{M} w_{M, i} \mid Y\right]\right]+\operatorname{Var}\left[\mathbb{E}\left[\sum_{i=1}^{M} w_{M, i} \mid Y\right]\right]\right) \\
& =C_{f}^{2} \operatorname{Var}\left[\sum_{i=1}^{M} w_{M, i}\right] \xrightarrow[M \rightarrow \infty]{M} 0 .
\end{align*}
$$

Step 2. We show that

$$
\begin{equation*}
\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right] \xrightarrow{M \rightarrow \infty} 0 \tag{S.96}
\end{equation*}
$$

where $X$ has density $\bar{p}(x)$. We start by writing

$$
\begin{align*}
& \operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right] \\
& =\mathbb{E}\left[\frac{f(X)^{2}}{\bar{p}(X)^{2}}\right]-\mathbb{E}\left[\frac{f(X)}{\bar{p}(X)}\right]^{2}-\mathbb{E}\left[\frac{f(Y)^{2}}{p_{Y}(Y)^{2}}\right]+\mathbb{E}\left[\frac{f(Y)}{p_{Y}(Y)}\right]^{2}  \tag{S.97}\\
& =\mathbb{E}\left[\frac{f(X)^{2}}{\bar{p}(X)^{2}}\right]-\mathbb{E}\left[\frac{f(Y)^{2}}{p_{Y}(Y)^{2}}\right] . \tag{S.98}
\end{align*}
$$

Since supp $Y \subset \operatorname{supp} \hat{p}$ (Equation 15) and we assume supp $\hat{p} \subset$ $\operatorname{supp} Y$, we have $\operatorname{supp} \hat{p}=\operatorname{supp} Y$. With $\operatorname{supp} \bar{p}=\operatorname{supp} \hat{p}$, we continue the above as

$$
\begin{aligned}
& =\int_{\operatorname{supp} Y} \bar{p}(x) \frac{f(x)^{2}}{\bar{p}(x)^{2}} \mathrm{~d} x-\int_{\text {supp } Y} p_{Y}(y) \frac{f(y)^{2}}{p_{Y}(y)^{2}} \mathrm{~d} y \\
& =\int_{\text {supp } Y} \bar{p}(y) \frac{f(y)^{2}}{\bar{p}(y)^{2}}-p_{Y}(y) \frac{f(y)^{2}}{p_{Y}(y)^{2}} \mathrm{~d} y \\
& =\int_{\text {supp } Y} p_{Y}(y)\left(\frac{f(y)^{2}}{\bar{p}(y)^{2}}\right)\left(\frac{\bar{p}(y)}{p_{Y}(y)}-\frac{\bar{p}(y)^{2}}{p_{Y}(y)^{2}}\right) \mathrm{d} y \\
& =\mathbb{E}\left[\frac{f(Y)^{2}}{\bar{p}(Y)^{2}}\left(\frac{\bar{p}(Y)}{p_{Y}(Y)}-\frac{\bar{p}(Y)^{2}}{p_{Y}(Y)^{2}}\right)\right],
\end{aligned}
$$

and thus,

$$
\begin{aligned}
& \left|\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]\right| \\
& \leq \mathbb{E}\left[\frac{f(Y)^{2}}{\bar{p}(Y)^{2}}\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-\frac{\bar{p}(Y)^{2}}{p_{Y}(Y)^{2}}\right|\right] \\
& \leq\|\hat{p}\|^{2} C_{f}^{2} \mathbb{E}\left[\left|\frac{\bar{p}(Y)}{p_{Y}(Y)}-\frac{\bar{p}(Y)^{2}}{p_{Y}(Y)^{2}}\right|\right] \\
& =\|\hat{p}\|^{2} C_{f}^{2} \mathbb{E}\left[\left|1-\left(1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right)\right|\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|\right] \\
& \leq\|\hat{p}\|^{2} C_{f}^{2} \mathbb{E}\left[\left(1+\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|\right)\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|\right] \\
& =\|\hat{p}\|^{2} C_{f}^{2}\left(\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|\right]+\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right]\right) \\
& \leq\|\hat{p}\|^{2} C_{f}^{2}\left(\sqrt{\mathbb{E}}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right]+\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right]\right) \\
& \xrightarrow{M \rightarrow \infty} 0
\end{aligned}
$$

by Theorem A. 2 (Item 2).
Step 3. Combining steps 1 and 2, we reach

$$
\begin{aligned}
& \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right] \\
= & \left(\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]\right)-\left(\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]\right) \\
& \xrightarrow{M \rightarrow \infty} 0 .
\end{aligned}
$$

Proof of Theorem A. 3 (Item 3). Substituting $\hat{p}(x)=C f(x)$, i.e., $\bar{p}(x)=f(x) /\|f\|$, to the previous result, yields

$$
\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(X)\|f\|}{f(X)}\right] \xrightarrow{M \rightarrow \infty} 0,
$$

i.e.,

$$
\operatorname{Var}\left[f(Y) W_{Y}\right] \xrightarrow{M \rightarrow \infty} 0 .
$$

## S.5.4 Variance in the Finite Case (Theorem 1)

Proof of Theorem 1. We continue the proof of Theorem A. 3 (Item 2) in Section S.5.3, and deduce

$$
\begin{aligned}
& \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right] \\
& =\operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]+\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right] \\
& \leq \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]+\left|\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]\right|
\end{aligned}
$$

We denote $V=\operatorname{Var}\left[\sum_{i=1}^{M} w_{i}\right]$ and derive from Equation S .88 in the proof of Theorem A. 2 that

$$
\begin{equation*}
\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right] \leq \frac{\operatorname{Var}\left[\hat{p}(Y) W_{Y}\right]}{\|\hat{p}\|^{2}}=\frac{V}{\|\hat{p}\|^{2}} \tag{S.101}
\end{equation*}
$$

We combine this with Equation S .99 to get

$$
\begin{align*}
& \left|\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]\right|  \tag{S.102}\\
& \left.\leq\|\hat{p}\|^{2} C_{f}^{2}\left(\sqrt{\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right.}\right]+\mathbb{E}\left[\left|1-\frac{\bar{p}(Y)}{p_{Y}(Y)}\right|^{2}\right]\right)  \tag{S.103}\\
& \leq\|\hat{p}\|^{2} C_{f}^{2}\left(\sqrt{\frac{V}{\|\hat{p}\|^{2}}}+\frac{V}{\|\hat{p}\|^{2}}\right)=C_{f}^{2}(\|\hat{p}\| \sqrt{V}+V) . \tag{S.104}
\end{align*}
$$

We then borrow from Equation S. 95 that

$$
0 \leq \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right] \leq C_{f}^{2} \operatorname{Var}\left[\sum_{i=1}^{M} w_{i}\right]=C_{f}^{2} V
$$

and reach

$$
\begin{align*}
& \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right] \\
& \leq \operatorname{Var}\left[f(Y) W_{Y}\right]-\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]+\left|\operatorname{Var}\left[\frac{f(Y)}{p_{Y}(Y)}\right]-\operatorname{Var}\left[\frac{f(X)}{\bar{p}(X)}\right]\right| \\
& \leq C_{f}^{2} V+C_{f}^{2}(\|\hat{p}\| \sqrt{V}+V)=C_{f}^{2} \sqrt{V}(\|\hat{p}\|+2 \sqrt{V}) . \tag{S.105}
\end{align*}
$$

Fig. 1. A parameter exploration of the number of initial samples per pixel ( $S$, colored lines) and the number of neighbors used for resampling (X-axis). Each pixel generates $S$ candidate samples and uses RIS to select one. Then GRIS resamples for each pixel a path from one from the neighboring $3 \times 3$, $5 \times 5,7 \times 7$, etc. pixels. Pairwise MIS is used.

Fig. 2. Sampling efficiency. This experiment repeats the setting of Figure 1, but outputs the MSE after ten seconds of rendering, revealing the most efficient parameters for multisample rendering.

## S. 6 PARAMETER EXPLORATION

In this section, we analyze the effect of parameters such as neighbor count, reuse window size and the number of spatial reuse passes for ReSTIR PT for offline rendering, justifying our choice of default parameters. We perform the experiments leading to our conclusions in two scenes, the simple Cornell Box and the more complex Kitchen scene.

We first demonstrate how sampling cost can be amortized by increasing the number of pixels we reuse from and the number of candidate path samples per pixel into optimal numbers. For the first experiment, we densely reuse paths from each pixel in a square around the current pixel, and after analyzing this case, we generalize the results to randomly sampled sparse neighbors from a larger neighborhood.

## S.6.1 Parameters for Dense Block of Pixels

Path reuse without GRIS (e.g., the path reuse algorithm by Bekaert et al. [2002]) can already achieve higher sampling efficiency than pure path tracing because resampling is cheaper than generating samples from scratch. By defining unbiased contribution weights,

Fig. 3. A comparison of 60 -second equal-time rendering of the Kitchen scene. Dense reuse and random reuse have similar MSE/MAPE with their respective optimal parameters, but random reuse produces results visually closer to the reference.
our GRIS supports more aggressive amortization of the sampling cost-with a reservoir, we can increase the number of input samples for the initial RIS to further amortize the sample generation cost. For $S$ candidate samples, we approximately "gain" $S$ samples when reusing one sample. To analyze the sampling efficiency, we form a simplified model that measures the ratio between the number of rays gained and the number of rays computed. Assuming a simplified ideal case where all pixels generate paths with a fixed length $L$ and reusing a neighbor effectively gains all samples it generates, we write the following equation for reusing $K$ pixels (including self),

$$
\begin{equation*}
\frac{\text { \# rays gained }}{\# \text { rays computed }}=\frac{K S L}{S L+\eta(K-1)}, \tag{S.106}
\end{equation*}
$$

where $\eta$ is the ray cost we pay for resampling (usually $\eta<L$ ).
If $S=1$, the equation evaluates to $K L /(L+\eta(K-1))$. Even when $K \rightarrow \infty$, the efficiency is still bounded by $L / \eta$. If we have $S \rightarrow \infty$, the efficiency is bounded by $K$, which means that the efficiency improvement becomes theoretically unlimited in this simplified ideal case. In practice, we can measure sampling efficiency by comparing the variance at equal render time.

This suggests that we should use a relatively large $S$ and a relatively large $K$ to achieve higher sampling efficiency. In practice, we observe in Figure 1 that increasing $S$ and $K$ eventually becomes harmful: increasing the neighbor count $K$ increases MSE instead of reducing it when the neighborhood becomes large enough, and a larger $S$ leads to problems even sooner. This is because enlarging the neighborhood size adds samples that are farther away, and path space similarity generally decreases by distance. This eventually offsets the benefit from more samples. Enlarging $S$ (the candidate count for initial resampling) can also eventually lead to diminishing returns, as we show in Figure 2. In both scenes, we see that using a combination of $S=32$ and $K=49$ (i.e., a $7 \times 7$ neighborhood) results in near-optimal sampling efficiency.

## S.6.2 Parameters for Sparse Neighbors

The cost of using a large number of input samples for GRIS can be amortized also by chaining multiple spatial reuse passes. A caveat is that chaining spatial reuse passes with a small, fixed neighborhood can lead to excessive correlation between the samples, which can
lead to reduced sampling efficiency. This motivates using sparse neighbors randomized from a larger neighborhood to minimize correlation.
From our parameter exploration, we found that near-optimal sampling efficiency for random reuse can be achieved with $S=32$ (similar to the dense reuse case), 2-3 rounds of spatial reuse with 6-10 random neighbors in 5-10 pixel radius (a diameter of 10-20 pixels). After comparing visual quality in this parameter range for both scenes, we select a parameter set of 10 pixel radius, 3 rounds of spatial reuse, and 6 random neighbors. We see a slight variance reduction in equal render time compared to dense reuse with its near-optimal parameters. The improvement of sampling efficiency is small, because sparse reuse requires a larger neighborhood to reduce correlation, which also lowers the similarity between the pixels. This partially cancels the benefits from amortizing the sampling cost. The visual improvement is, however, much larger (Figure 3), since random reuse reduces visual correlation between nearby pixels. We find the 10 -pixel radius can still be enlarged for real-time rendering, as chaining many reuse passes over multiple frames builds up more correlation. For real-time rendering, we use a radius of 20 pixels, only one initial candidate sample per pixel, and one spatial reuse pass between the current pixel and three random others, to keep the rendering time low.

## S. 7 MATHEMATICAL NOTES

## S.7.1 Constraints on $w_{i}$ for Zero Bias in Section 4.3

We assume, according to the section, that

$$
g_{i}(x)=\left[x \in \mathcal{D}\left(T_{i}\right)\right] c_{i}\left(y_{i}\right) \cdot f\left(y_{i}\right)\left|\frac{\partial T_{i}}{\partial x}\right|,
$$

where $y_{i}$ is a shorthand for $T_{i}(x)$, and [•] is 1 if $\cdot$ is true and 0 otherwise, and that either

- (easy case) $w_{i}>0$ exactly when $X_{i} \in \mathcal{D}\left(T_{i}\right)$ and $Y_{i}=$ $T_{i}\left(X_{i}\right) \in \operatorname{supp} \hat{p}$, otherwise $w_{i}=0$, or
- (general case) $w_{i}$ are also allowed to be 0 also when $c_{i}\left(Y_{i}\right)=$ 0 or $W_{i}=0$, and Equation 17 holds for all $y \in \operatorname{supp} \hat{p} \cap$ $\bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$.
Then, we show that the derived estimator is unbiased,

$$
\begin{equation*}
E\left[g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} f\left(X_{s}\right) W_{s}\right]=\int_{\operatorname{supp} Y} f(y) \mathrm{d} y, \tag{S.107}
\end{equation*}
$$

and that Equation 15 holds, i.e.,

$$
\begin{equation*}
\operatorname{supp} Y=\operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right) . \tag{S.108}
\end{equation*}
$$

Let us first prove Equation S. 108 in both cases.
Proof. Easy case. If $y \in \operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$, then $y=$ $T_{i}\left(x_{i}\right)$ for some $x_{i} \in \operatorname{supp} X_{i}$ where $x_{i}$ can be sampled with a positive PDF. Since also $y \in \operatorname{supp} \hat{p}$, we have $\hat{p}(y)=\hat{p}\left(T_{i}\left(x_{i}\right)\right)>0$, and therefore by assumption $w_{i}>0$. Thus, we have an $x_{i}$ with positive PDF, $w_{i}>0$, and $y=T_{i}\left(x_{i}\right)$, and we have a way of sampling $y$ with a positive PDF, i.e., $y \in \operatorname{supp} Y$. We showed that $\operatorname{supp} \hat{p} \cap$ $\bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right) \subset \operatorname{supp} Y$.

If, on the other hand, $y \in \operatorname{supp} Y$, the PDF of sampling $y$ is positive. Thus, there exists an $x_{i}$ with a positive PDF and a positive selection probability for $y=T_{i}\left(x_{i}\right)$. Hence $w_{i}>0$, which implies $\hat{p}(y)>0$, and hence $y \in \operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$. Combined with the previous, we have supp $Y=\operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$.

General case. Let $y \in \operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$. Let $I$ be the set of indices for which $y \in T_{i}\left(\operatorname{supp} X_{i}\right)$. Since $\sum_{i \in I} c_{i}(y)=1$ by assumption, there exists at least one $i$ such that $c_{i}(y)>0$, and therefore an $x_{i}$ such that $y=T_{i}\left(x_{i}\right)$ with $p_{X_{i}}\left(x_{i}\right)>0$. Since $0<$ $p_{X_{i}}\left(x_{i}\right)=1 / \mathbb{E}\left[W_{i} \mid X_{i}=x_{i}\right]$, the conditional expectation of $W_{i}$ is positive and hence $\operatorname{Pr}\left[W_{i}>0 \mid X_{i}=x_{i}\right]>0$ and $p_{Y}(y)>0$, i.e., $y \in \operatorname{supp} Y$.

Assume then that $y \in \operatorname{supp} Y$. The PDF of generating $y$ is positive, so there have to exist $i$ and $x_{i} \in \Omega_{i}$ such that $p_{X_{i}}\left(x_{i}\right)>0, y=$ $T_{i}\left(x_{i}\right)$, and with a positive conditional probability $w_{i}>0$. If $w_{i}$ may be positive, it follows that $y \in \operatorname{supp} \hat{p}$, and hence $y \in \operatorname{supp} \hat{p} \cap$ $\bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$. Combined with the previous, we have supp $Y=$ $\operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)$.

Next, we will prove Equation S.107.

Proof. First,

$$
\begin{align*}
& \mathbb{E}\left[g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} W_{s}\right]  \tag{S.109}\\
& =\mathbb{E}\left[\sum_{s=1}^{M}\left[w_{s}>0\right] \frac{w_{s}}{\sum_{j=1}^{M} w_{j}} g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} w_{s}\right]  \tag{S.110}\\
& =\mathbb{E}\left[\sum_{s=1}^{M}\left[w_{s}>0\right] g_{s}\left(X_{s}\right) w_{s}\right] \tag{S.111}
\end{align*}
$$

Next, we substitute the definition of $g_{s}$ and reach

$$
\begin{equation*}
=\mathbb{E}\left[\sum_{s=1}^{M}\left[w_{s}>0\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] \tag{S.112}
\end{equation*}
$$

We add in the assumption which holds in both cases, $w_{s}=0$ if $\hat{p}\left(Y_{S}\right)=0$, and reach

$$
\begin{equation*}
=\mathbb{E}\left[\sum_{s=1}^{M}\left[Y_{S} \in \operatorname{supp} \hat{p}\right]\left[w_{s}>0\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] \tag{S.113}
\end{equation*}
$$

Next we substitute $\left[w_{s}>0\right]=1-\left[w_{s}=0\right]$, and reach

$$
\begin{align*}
= & \mathbb{E}\left[\sum_{s=1}^{M}\left[Y_{s} \in \operatorname{supp} \hat{p}\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] \\
& -\mathbb{E}\left[\sum_{s=1}^{M}\left[Y_{s} \in \operatorname{supp} \hat{p}\right]\left[w_{s}=0\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] . \tag{S.114}
\end{align*}
$$

Using the definition of unbiased contribution weights (everything except $W_{S}$ is a function of $X_{S}$ ), we get for the first term,

$$
\begin{align*}
& \mathbb{E}\left[\sum_{s=1}^{M}\left[Y_{s} \in \operatorname{supp} \hat{p}\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] \\
& =\sum_{s=1}^{M} \int_{\operatorname{supp} X_{s}}\left[y_{s} \in \operatorname{supp} \hat{p}\right]\left[x_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(y_{s}\right) f\left(y_{s}\right)\left|\frac{\partial T_{s}}{\partial x_{s}}\right| \mathrm{d} x_{s}  \tag{S.116}\\
& =\sum_{s=1}^{M} \int_{\mathcal{D}\left(T_{s}\right)}\left[y_{s} \in \operatorname{supp} \hat{p}\right]\left[x_{s} \in \operatorname{supp} X_{s}\right] c_{s}\left(y_{s}\right) f\left(y_{s}\right)\left|\frac{\partial T_{s}}{\partial x_{s}}\right| \mathrm{d} x_{s}, \tag{S.117}
\end{align*}
$$

which, with a change of variables $y=T_{s}\left(x_{s}\right)$ for each of the terms, and then denoting $x_{s}=T_{s}^{-1}(y)$, simplifies into

$$
\begin{align*}
& =\sum_{s=1}^{M} \int_{\mathcal{I}\left(T_{s}\right)}[y \in \operatorname{supp} \hat{p}]\left[x_{s} \in \operatorname{supp} X_{S}\right] c_{s}(y) f(y) \mathrm{d} y  \tag{S.118}\\
& =\sum_{s=1}^{M} \int_{\operatorname{supp} \hat{p}}\left[y \in \mathcal{I}\left(T_{S}\right)\right]\left[x_{s} \in \operatorname{supp} X_{S}\right] c_{S}(y) f(y) \mathrm{d} y  \tag{S.119}\\
& =\int_{\operatorname{supp} \hat{p}}\left(\sum_{s=1}^{M}\left[y \in \mathcal{I}\left(T_{S}\right)\right]\left[x \in \operatorname{supp} X_{S}\right] c_{S}(y)\right) f(y) \mathrm{d} y \tag{S.120}
\end{align*}
$$

We then write the product of the brackets as a summation condition and reach

$$
\begin{align*}
& =\int_{\operatorname{supp} \hat{p}}\left(\sum_{\substack{s=1 \\
y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M} c_{s}\left(y_{s}\right)\right) f(y) \mathrm{d} y  \tag{S.121}\\
& \left.=\int_{\operatorname{supp} \hat{p} \cap \cup_{i} T_{i}\left(\operatorname{supp} X_{i}\right)} \sum_{\substack{s=1 \\
y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M} c_{s}\left(y_{s}\right)\right) f(y) \mathrm{d} y  \tag{S.122}\\
& =\int_{\operatorname{supp} Y}\left(\sum_{\substack{s=1 \\
y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M} c_{s}(y)\right) f(y) \mathrm{d} y  \tag{S.123}\\
& =\int_{\operatorname{supp} Y} f(y) \mathrm{d} y . \tag{S.124}
\end{align*}
$$

For the method be unbiased for integrating $f$ over supp $Y$, the second term,
$\mathbb{E}\left[\sum_{s=1}^{M}\left[Y_{s} \in \operatorname{supp} \hat{p}\right]\left[w_{s}=0\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right] c_{s}\left(Y_{s}\right) f\left(Y_{S}\right)\left|\frac{\partial T_{S}}{\partial X_{s}}\right| W_{S}\right]$, must be zero.

For the easier case, $w_{i}>0$ if and only if $X_{i} \in \mathcal{D}\left(T_{i}\right)$ and $Y_{i}=$ $T_{i}\left(X_{i}\right) \in \operatorname{supp} \hat{p}$. The above second term contains for each $s$ the factor

$$
\begin{align*}
& {\left[Y_{s} \in \operatorname{supp} \hat{p}\right]\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right]\left[w_{s}=0\right]}  \tag{S.126}\\
& =\left[w_{s}>0\right]\left[w_{s}=0\right]=0 \tag{S.127}
\end{align*}
$$

and thus the second term is zero and the estimator is unbiased.
For the general case, $w_{i}$ is additionally allowed to be 0 when either $W_{i}=0$ or $c_{i}\left(Y_{i}\right)=0$. The second term is also then zero: for it to be non-zero, we need to have $w_{s}=0$ for some $s$. However, if $w_{s}=0$, then by assumption, either $X_{s} \notin \mathcal{D}\left(T_{s}\right), Y_{s} \notin \operatorname{supp} \hat{p}, c_{s}\left(Y_{s}\right)=0$, or $W_{s}=0$. It is easy to check all these cases: in all cases the second term is zero. The estimator is unbiased.

## S.7.2 Non-Negativity of $m_{i}$ and $W_{i}$ in Section 4.4

Here we prove that in Equation 19, we must require $m_{i} \geq 0$ and $W_{i} \geq 0$ to guarantee non-negative probabilities.

Proof. The selection probabilities $\operatorname{Pr}[s=i]=w_{i} / \sum_{j=1}^{M} w_{j}$ all need to be non-negative. They are divided by the same denominator, which flips the sign of either none or all the $w_{i} / \sum_{j=1}^{M} w_{j}$ expressions. Therefore, all $w_{i}$ must have the same sign, so that the probabilities can all be non-negative. If we had $w_{i} \leq 0$ for all $i$, we could simply flip the signs of the $w_{i}$ to reach $w_{i} \geq 0$; without loss of generality, we restrict ourselves to the case $w_{i} \geq 0$.

If it is the case that $w_{i} \geq 0$, then it is also the case that

$$
\begin{equation*}
\mathbb{E}\left[w_{i} \mid X_{i}\right] \geq 0 \tag{S.128}
\end{equation*}
$$

almost surely.

Next, we substitute Equation 19 for $w_{i}$. If $x \notin \mathcal{D}\left(T_{i}\right)$, we have $w_{i}=0$. Otherwise, denoting $y=T_{i}(x)$ and $Y_{i}=T_{i}\left(X_{i}\right)$, we must have

$$
\begin{align*}
0 \leq \mathbb{E}\left[w_{i} \mid X_{i}=x\right] & =\mathbb{E}\left[\left.m_{i}\left(Y_{i}\right) \hat{p}\left(Y_{i}\right) W_{i}\left|\frac{\partial T_{i}}{\partial X_{i}}\right| \right\rvert\, X_{i}=x\right]  \tag{S.129}\\
& =m_{i}(y) \hat{p}(y)\left|\frac{\partial T_{i}}{\partial x}\right| \mathbb{E}\left[W_{i} \mid X_{i}=x\right]  \tag{S.130}\\
& =m_{i}(y) \hat{p}(y)\left|\frac{\partial T_{i}}{\partial x}\right| \frac{1}{p_{X_{i}}(x)} . \tag{S.131}
\end{align*}
$$

Since $\hat{p}(y),\left|\frac{\partial T_{i}}{\partial x}\right|$ and $p_{X_{i}}(x)$ are all non-negative and the full product is non-negative, $m_{i}(y)$ must also be non-negative.

Looking at Equation 19, since we have $m_{i} \geq 0, \hat{p}(y) \geq 0$ and $\left|\frac{\partial T_{i}}{\partial x}\right| \geq 0$, and their product with $W_{i}$ is $w_{i} \geq 0$, we must also have $W_{i} \geq 0$.

## S.7.3 Resampling MIS Must Be Positive in Support of $c_{i}$ in Section 4.4

To guarantee unbiased integration, the resampling MIS weights $m_{i}$ must fulfill $m_{i}(y)>0$ whenever $c_{i}(y) \neq 0$ in addition to nonnegativity and Equation 20:

Proof. Substituting $g_{i}$ into the left-hand-side of Equation 10 yields

$$
\begin{align*}
& \mathbb{E}\left[g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} W_{s}\right]=\mathbb{E}\left[\left[w_{s}>0\right] g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} W_{s}\right]  \tag{S.132}\\
& =\mathbb{E}\left[\sum_{s=1}^{M}\left[w_{s}>0\right] \frac{w_{s}}{\sum_{j=1}^{M} w_{j}} g_{s}\left(X_{s}\right) \frac{\sum_{j=1}^{M} w_{j}}{w_{s}} W_{s}\right]  \tag{S.133}\\
& =\sum_{s=1}^{M} \mathbb{E}\left[\left[w_{s}>0\right] g_{s}\left(X_{s}\right) W_{s}\right] . \tag{S.134}
\end{align*}
$$

We know that $w_{s}$ (Equation 19) is positive if and only if $X_{s} \in \mathcal{D}\left(T_{s}\right)$, $m_{s}\left(Y_{s}\right)>0, \hat{p}\left(Y_{s}\right)>0, W_{s}>0$ and $\left|\frac{\partial T_{s}}{\partial X_{s}}\right|>0$. We assume $W_{s} \geq$ 0 , and the case $W_{s}=0$ is already handled by the factor $W_{s}$. The Jacobian determinant is nonzero with probability 1 in $\mathcal{D}\left(T_{i}\right)$ since $T_{i}$ is bijective. Hence, substituting $g_{s}$, we reach

$$
=\sum_{s=1}^{M} \mathbb{E}\left[\left[X_{s} \in \mathcal{D}\left(T_{s}\right)\right]\left[m_{s}\left(Y_{s}\right), \hat{p}\left(Y_{s}\right)>0\right] c_{s}\left(Y_{s}\right) f\left(Y_{s}\right)\left|\frac{\partial T_{s}}{\partial X_{s}}\right| W_{s}\right] .
$$

Everything left from the unbiased contribution weight $W_{s}$ is a function of $X_{s}$. Hence, by the definition of unbiased contribution weights, we reach

$$
=\sum_{s=1}^{M} \int_{\operatorname{supp} X_{s}}\left[x_{s} \in \mathcal{D}\left(T_{s}\right)\right]\left[m_{s}\left(y_{s}\right), \hat{p}\left(y_{s}\right)>0\right] c_{s}\left(y_{s}\right) f\left(y_{s}\right)\left|\frac{\partial T_{s}}{\partial x_{s}}\right| \mathrm{d} x_{s} .
$$

Swapping the integration domain and $\left[x_{s} \in \mathcal{D}\left(T_{s}\right)\right]$, we reach

$$
=\sum_{s=1}^{M} \int_{\mathcal{D}\left(T_{s}\right)}\left[x_{s} \in \operatorname{supp} X_{s}\right]\left[m_{s}\left(y_{s}\right), \hat{p}\left(y_{s}\right)>0\right] c_{s}\left(y_{s}\right) f\left(y_{s}\right)\left|\frac{\partial T_{s}}{\partial x_{s}}\right| \mathrm{d} x_{s},
$$

and the change of variables $y=T_{s}\left(x_{s}\right)$ yields

$$
=\sum_{s=1}^{M} \int_{I\left(T_{s}\right)}\left[x_{s} \in \operatorname{supp} X_{s}\right]\left[m_{s}(y), \hat{p}(y)>0\right] c_{s}(y) f(y) \mathrm{d} y .
$$

Swapping the integration domain and $[\hat{p}(y)>0]$ yields

$$
=\sum_{s=1}^{M} \int_{\operatorname{supp} \hat{p}}\left[x_{s} \in \operatorname{supp} X_{s}\right]\left[y \in \mathcal{I}\left(T_{s}\right)\right]\left[m_{s}(y)>0\right] c_{s}(y) f(y) \mathrm{d} y,
$$

which allows moving the sum inside the integral:

$$
=\int_{\operatorname{supp} \hat{p}}\left(\sum_{s=1}^{M}\left[x_{s} \in \operatorname{supp} X_{s}\right]\left[y \in \mathcal{I}\left(T_{s}\right)\right]\left[m_{s}(y)>0\right] c_{s}(y)\right) f(y) \mathrm{d} y .
$$

Next, we simplify the first two indicators into the summation condition:

$$
\begin{equation*}
=\int_{\operatorname{supp} \hat{p}}\left(\sum_{\substack{s=1 \\ y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M}\left[m_{s}(y)>0\right] c_{s}(y)\right) f(y) \mathrm{d} y . \tag{S.135}
\end{equation*}
$$

The integrand is zero unless the sum contains at least one index and we can shrink the integration domain accordingly:

$$
\left.=\int_{\operatorname{supp} \hat{p} \cap \bigcup_{i=1}^{M} T_{i}\left(\operatorname{supp} X_{i}\right)} \sum_{\substack{s=1 \\ y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M}\left[m_{s}(y)>0\right] c_{s}(y)\right) f(y) \mathrm{d} y .
$$

By Equation 15, this domain is exactly $\operatorname{supp}(Y)$ :

$$
\begin{equation*}
=\int_{\operatorname{supp} Y}\left(\sum_{\substack{s=1 \\ y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M}\left[m_{s}(y)>0\right] c_{s}(y)\right) f(y) \mathrm{d} y . \tag{S.136}
\end{equation*}
$$

Finally, if we assume $m_{s}(y)>0$ whenever $c_{s}(y) \neq 0$, by the constraint of the contribution MIS weights (Equation 17), we reach

$$
\begin{align*}
& =\int_{\operatorname{supp} Y}\left(\sum_{\substack{s=1 \\
y \in T_{s}\left(\operatorname{supp} X_{s}\right)}}^{M} c_{s}(y)\right) f(y) \mathrm{d} y  \tag{S.137}\\
& =\int_{\operatorname{supp} Y} f(y) \mathrm{d} y . \tag{S.138}
\end{align*}
$$

If we assumed a non-zero probability that $m_{s}(y)=0$ while $c_{s}(y) \neq 0$, the multiplier in front of $f(y)$ in Equation S. 136 would not simplify to 1 with the constraints of $c_{i}$, and the result would be wrong. $\quad \square$
